1. EBL investigations: the investigation report, including the water information, should be provided to the MDHHS Healthy Homes Section within two weeks on average after the investigation is completed. This includes time for receipt of specimen test results (water, dust wipes, soil).
2. Elevated EBLs: there were 18 children with elevated EBLs shown in the summary report as of October 30, 2015. I have the more detailed age breakdown for the updated report which would show data from 10/1/2015 to 11/13/2015. There are 22 children with elevated EBLs. Of children < 6, 14 have levels 5 – 14, 2 have levels 15 – 44. Among children 6 to 17 years, 5 have levels 5 – 14 and 1 has a level 15 – 44. In summary, 19 children fall into the 5 – 14 category and 3 in the 15 -44 category. So most kids are in the 5 – 14 mcg/dL category if they have elevated EBLs. The table is attached. Epidemiology is not planning on sending these more detailed tables up to you routinely, but this table gives you a feel for the testing by age group and whether or not the test, if known, is venous or capillary.
